COVID-19 Antibody Total, Serum, Plasma, or Whole Blood (Lab Tests and Diagnostic Procedures)

Comment

The FDA has noted that unauthorized fraudulent COVID-19 test kits are being sold online. Currently the only way to be tested for COVID-19 is through licensed health care providers. The FDA advises consumers and health professionals to be cautious of websites and stores selling products that claim to prevent, diagnose, treat, or cure COVID-19 (FDA 2020). Consumers and health care professionals can help by reporting suspected fraud to the FDA’s Health Fraud Program or the Office of Criminal Investigations.

Overview

At the end of 2019, a novel coronavirus was identified as the cause of several cases of pneumonia in Wuhan City, Huber Province, China. Initially linked to a large seafood and animal market suggesting animal-to-human spread, person-to-person transmission was quickly confirmed (Li Q 2020). The virus spread rapidly worldwide and in January 2020, the World Health Organization (WHO) declared the outbreak a "public health emergency of international concern." On March 11, 2020, the WHO publicly characterized COVID-19 as a pandemic. Currently, more than 100 million infections have been confirmed globally in over 200 countries and territories with over 3 million deaths (WHO situation rept 2021).

The novel virus has been named severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) and the disease it causes has been named coronavirus disease 2019 (COVID-19). The virus is thought to spread mainly by larger respiratory droplets (and less commonly, small aerosol droplets) produced when an infected person exhales (eg, breathes, speaks, coughs, sneezes, or sings). The droplets can land in the mouths, noses and eyes of nearby people, or possibly be inhaled into the lungs. Touching a contaminated surface and transferring to eyes, nose or mouth is also thought to be a mode of transmission although not as efficient as by respiratory droplets. Symptoms typically appear within 2 to 14 days (median of 5 days) of exposure and include fever, chills, fatigue, cough, shortness of breath,
myalgia, recent loss of taste or smell, vomiting or diarrhea, and/or sore throat. Sickness ranges from a mild respiratory illness to severe disease including respiratory failure, septic shock, or other organ failure. Most fatalities have occurred in patients with underlying comorbidities, with overall global fatalities around 2 to 3 percent (WHO situation rept 2021). The CDC currently estimates that about 30% of COVID-19 infections are asymptomatic, and 50% of transmission occurs prior to symptom onset (CDC Pandemic Planning 2020).

Although molecular nucleic acid polymerase chain reaction tests have become the current gold standard method for diagnosis of SARS-CoV-2 infection (see COVID-19, PCR, Respiratory Specimen), there is also a need for antibody assays to assist in identifying infected patients, asymptomatic carriers, and exposed individuals, thus assuring timely treatment of patients, helping to prevent virus transmission, and determining depth of population exposure. The FDA has issued Emergency Use Authorizations (EUA) for the qualitative detection of total antibodies to SARS-CoV-2. These assays are intended for detecting individuals with an adaptive immune response to SARS-CoV-2.

Use/Indications

Aid in the identification of individuals who have been exposed and/or recovered from SARS-CoV-2 infection by identifying an immune response. Antibody assays should not be used to diagnose acute SARS-CoV-2 infection. It is recommended to use a viral (nucleic acid or antigen) test to diagnose acute infection (CDC 2021 Overview of Testing).

- Support diagnosis of COVID-19 illness for patients who present later in infection (≥7 days). Serologic testing should be offered in addition to recommended molecular testing (CDC Interim Guidelines 2021). During this time period, the sensitivity of nucleic acid detection is decreasing, and the sensitivity of serologic testing is increasing.
  - A positive antibody test in a symptomatic patient (with negative viral test) at least 7 days post symptom onset. The CDC recommends proof of seroconversion (ie, two antibody tests, a negative result on initial specimen converting to a positive result on second specimen).
- Assessment of multisystem inflammatory syndrome (in both children and adults) (CDC Interim Guidelines 2021; IDSA [Hanson] 2020).
- Serosurveillance studies (IDSA [Hanson] 2020).

IgG and IgM antibodies rise (almost) simultaneously and are detectable 1 to 3 weeks post symptom onset. IgG antibodies persist longer than other antibodies. As the time between infection and antibody testing increases, assays that measure IgG and total antibody may have more sensitivity. When laboratory confirmation is needed for clinical or epidemiological purposes, the IDSA [Hanson 2020] recommends IgG antibody or total antibody 3 to 4 weeks after symptom onset to detect evidence of past SARS-CoV-2 infection.

Test Includes

Qualitative detection of total SARS-CoV-2 antibodies. Depending on manufacturer, this may include total IgG and IgM or total IgG, IgM, and IgA antibodies.
Contraindications

Although some individuals (23% to 63%) will develop antibodies within the first week of symptom onset, the IDSA recommends against serologic testing during the first two weeks (14 days) following symptom onset due to variable sensivities and specificities of available assays (IDSA [Hanson 2020]).

Assessing immunity to COVID-19 following vaccination or assessing the need for vaccination in an unvaccinated person via antibody testing is not currently recommend (CDC Interim Guidelines 2021).

Test should not be used for screening of donated blood for the purpose of preventing COVID-19 transmission.

Specimen

Serum, plasma, or venous whole blood (manufacturer dependent)

Container(s)

- Serum separator tube or red top (no additive) tube

Alternate Container(s)

- Confer with testing laboratory for appropriate alternate container(s).
- Green top (lithium heparin) tube
- Green top (sodium heparin) tube
- Lavender top (EDTA) tube
- Light blue top (sodium citrate) tube

Volume / Minimum Volume

Tube filled to capacity or 1 mL blood (0.5 mL serum or plasma)

Collection

Prior to specimen collection, patient identity should be confirmed using two independent identifiers; use of a patient identification arm band or similar system is recommended. Specimen label(s) should include the two independent identifiers and the date of collection. There should be a method to identify the individual collecting the specimen. The specimen container(s) should be labeled in the presence of the patient after specimen is collected. Container(s) should not be prelabeled. Use computer-generated label(s), if available, to avoid transcription errors.

Routine venipuncture, using appropriate personal protective equipment; transport to laboratory immediately.

Processing and Storage

- Allow serum separator tube or red top (no additive) tube to clot completely at room temperature. Centrifuge clotted or anticoagulated specimen within 2 hours of collection and transfer serum or plasma into clean, plastic vial and refrigerate or freeze.
• Refer to manufacturer instructions.
• Whole blood specimen should be tested immediately.

**Stability**

• Room temperature: 8-72 hours (manufacturer dependent)
• Refrigerated: 2-7 days (manufacturer dependent)
• Frozen for longer storage: Not established to 1 month

**Causes for Rejection**

Fingerstick whole blood is not acceptable.

**Methodology**

Microsphere Immunoassay (MIA) measured by fluorescence; Lateral Flow (LF); Enzyme-linked Immunosorbent Assay (ELISA) with chromogenic or electrochemiluminescence detection

**Normal Values/Findings**

Negative or nonreactive

All positives must be reported to local/state health departments.

**Interpretative Information**

Results from antibody testing should not be used as the sole basis to diagnose or rule out SARS-CoV-2 infection. Results should be used in conjunction with other data including symptoms, results of other tests, and clinical impression.

• A positive test indicates detection of antibodies to SARS-CoV-2 and is consistent with a recent or previous SARS-CoV-2 infection.

• A negative result suggests absence of detectable antibodies to SARS-CoV-2, however, this does not preclude SARS-CoV-2 infection and should not be the sole basis for patient management decisions. A negative result can occur if antibody level is below the assay limit of detection, or if antibodies are not present during disease stage in which the sample was collected (eg, too early in the infection cycle [prior to IgG seroconversion] or due to a decline in titer over time). For patients who have been in contact with known infected individuals, have been in areas with high prevalence of active infection, or are experiencing symptoms consistent with COVID-19, a molecular diagnostic test is necessary to rule out infection.

• It is important to note, as very little is known about protective immunity of SARS-CoV-2 antibodies, serology results should not be used to establish immunity, make staffing decisions or decisions regarding the need for personal protective equipment.

**Limitations**

• In patients tested too early during infection, antibody levels may be below level of detection despite active infection, thus yielding false-negative results.
• Immunocompromised patients may have a delayed antibody response to COVID-19 and produce levels of antibody below the assay level of detection.

• Viral amino acid mutations in the epitope recognized by the antibody utilized in the test can cause false negative results (Vitros 2020).

• False-positive results due to cross-reactivity may occur with other coronaviruses including common cold coronaviruses (HKU1, NL63, OC43, 229E), and SARS-CoV-1 and MERS-CoV (Platelia 2020; Dimension 2020).

• A positive result may not indicate previous SARS-CoV-2 infection. Clinical history and local disease prevalence should be considered in assessing the need for a second, but different antibody test to confirm immune response.

• The presence of heterophilic antibodies in patient specimen can interfere with immunoassay (Vitros 2020).

• Presence of biotin can interfere with assays that use biotinylated reagents (FDA New York 2020)

Diagnostic Role

Current antibody testing can help identify patients who previously had SARS-CoV-2 infection as well as patients with current infection who have had symptoms for several days to weeks. However, due to variability in detectable antibody levels in early stage disease, there is limited utility for diagnosis of acute infection with antibody testing.

Thus far, serologic correlates of protective immunity are not fully understood, but current evidence indicates that production of antibodies following SARS-CoV-2 infection confers some portion of immunity to reinfection for at least three to six months (CDC Interim Guidelines 2021; Lumley 2021; Hall 2020). The robustness and durability of natural-infection immunity, how it compares to vaccine-induced immunity, and the impact of emerging viral variants are currently unknown and under study.

Because SARS-CoV-2 infection can be asymptomatic or minimally symptomatic, the official tally of actual infections is probably substantially underestimated. Large-scale serologic screening with validated tests may be able to provide a better measure of disease activity.

Laboratory/Diagnostic Pearls

• Antibodies to SARS-CoV-2, typically detected 1 to 3 weeks post symptom onset, have been reported in patients with mild and severe disease. The antibody response is more robust (higher titers and longer persistence) in those with severe disease (Rijkers 2020). How long the antibodies persist after infection is unknown but they appear to persist for several months in most (Dan 2021).

• Studies indicate SARS-CoV-2 may persist on surfaces for a few hours up to several days dependent on conditions (eg, type of surface, temperature or humidity of the environment). Warmer temperatures and exposure to sunlight reduces viral survival time (CDC Environment 2020).

Additional Information
The major antigenic targets of SARS-CoV-2 virus that induce antibody response are:

1. Spike glycoprotein (S) which is responsible for receptor binding and membrane fusion for viral entry into the host cell.

2. Nucleocapsid phosphoprotein (N), an immunodominant antigen (or protein) of the CoV family that interacts with RNA.
